

AAVE Bible Concordance - App Summary

Evidence source: README.md, Docs/*.md, and implementation files in this repo.

What it is

A SwiftUI iOS Bible-reading app focused on Scripture access in AAVE with optional traditional translation comparison and commentary support. The product is positioned as a reading and discipleship tool with local-first content for reliable access.

Who it's for

Primary persona: everyday believers who want clear Scripture reading plus commentary in culturally fluent language (Docs/PRD.md).

What it does

- Five-tab navigation: Home, Bible, Search, Bookmarks, and More (Views/MainView.swift).
- Loads bundled AAVE Bible and commentary JSON from app resources for baseline offline reading (Views/Services/TranslationService.swift).
- Supports verse/chapter reading with commentary drill-in and deep-link navigation to verse detail (Views/MainView.swift).
- Provides search and direct navigation to book/chapter/verse results with empty/loading states (Views/SearchView.swift).
- Lets users save/manage bookmarks, highlights, and notes with local persistence (Views/BookmarkView.swift, Views/Services/UserDataManager.swift).
- Schedules verse-of-day and related notifications, with optional lock-screen live activity updates (Views/Services/NotificationManager.swift).
- Includes quiz scoring and leaderboard-related Firebase/Firestore integrations (Views/Services/FirestoreService.swift, Docs/TECH_STACK.md).

How it works (architecture from repo evidence)

- UI layer: SwiftUI app entry injects shared state/services (settings, network monitor, notification manager, router, auth manager).
- Core content: TranslationService discovers bundled AAVE/commentary JSON, loads content in memory, and builds a local search index.
- Verse retrieval flow: VerseManager routes AAVE requests to TranslationService; non-AAVE requests go to BibleAPIService (labs.bible.org), with local file/cache support for downloaded books.
- State + personalization: UserDefaults-backed services persist reading history, notes, bookmarks/highlights, progress streaks, and simple rule-based personalization.
- Remote integrations: AppDelegate configures Firebase (Auth, Messaging); FirestoreService persists quiz scores. Detailed crash-reporting setup: Not found in repo.

How to run (minimal)

- Open `AAVE Bible Concordance.xcodeproj` in Xcode.
- Ensure local Firebase config exists if you need auth/leaderboard/push features (`AAVE Bible Concordance/GoogleService-Info (1).plist`).
- Build and run on simulator/device, or run: `xcodebuild -project "AAVE Bible Concordance.xcodeproj" -scheme "AAVE Bible Concordance" -destination 'generic/platform=iOS' build`.
- Exact CI pipeline and release process: Not found in repo.
